An *hp*-version interior penalty discontinuous Galerkin method (DGFEM) for the numerical solution of second-order elliptic partial differential equations on general computational meshes consisting of polygonal/polyhedral elements is presented and analyzed. Utilizing a bounding box concept, the method employs elemental polynomial bases of total degree p (\mathcal{P}_p -basis) defined on the physical space, without the need to map from a given reference or canonical frame. This, together with a new specific choice of the interior penalty parameter which allows for face-degeneration, ensures that optimal *a priori* bounds may be established, for general meshes including polygonal elements with degenerating edges in two dimensions and polyhedral elements with degenerating faces and/or edges in three dimensions. Numerical experiments highlighting the performance of the proposed method are presented. Moreover, the competitiveness of the p -version DGFEM employing a \mathcal{P}_p -basis in comparison to the conforming p -version finite element method on tensor-product elements is studied numerically for a simple test problem.

Keywords: Discontinuous Galerkin; polygonal elements; polyhedral elements; *hp*-finite element methods; inverse estimates; P -basis.

AMS Subject Classification: 65N30, 65N50, 65N55

1. Introduction

The origins of the discontinuous Galerkin finite element method (DGFEM, for short) can be traced back almost half a century ago to the work undertaken on the

weak enforcement of Dirichlet boundary conditions for second-order elliptic partial differential equations; see, for example, Refs. 15, 19, 53 and 58. In particular, we highlight the works of Nitsche and Baker, see Refs. 58 and 20, respectively, which form the basis of the now popular class of so-called interior penalty (IP) DGFEMs, cf. also Refs. 11 and 70. Independently, DGFEMs were formulated for the numerical solution of first-order hyperbolic problems in the early '70s by Reed and Hill in Ref. 60; see also Ref. 52. Despite this early progress on DGFEMs, much of the subsequent research in the field of numerical analysis of partial differential equations concentrated on the development and analysis of conforming finite element methods for self-adjoint elliptic problems, stabilized continuous finite element methods for convection–diffusion equations, and finite difference and finite volume methods for hyperbolic problems. However, the past couple of decades have witnessed a resurgence of interest in discontinuous schemes. Indeed, tremendous progress has been made on both the analytical and computational aspects of DGFEMs; for a review of some of the main developments in the subject, we refer to the recent monographs in Refs. 38, 39, 46 and 61. For a historical review of DGFEMs, we refer to the articles in Refs. 14 and 37.

This paradigm shift has been stimulated by a number of important factors. In the context of nonlinear hyperbolic conservation laws, DGFEMs have a number of important advantages over well-established finite volume methods. The concept of higher-order discretization is inherent to the DGFEM. Moreover, the stencil is minimal in the sense that each element communicates only with its direct neighbors. In particular, in contrast to the increasing stencil size needed to increase the accuracy of classical finite volume methods, the stencil of DGFEMs is the same for any order of accuracy which has important advantages for the implementation of boundary conditions and for the parallel efficiency of the method. As for finite volume methods, DGFEMs are, by construction, locally conservative. Moreover, DGFEMs can naturally treat convection-dominated diffusion problems without excessive numerical stabilization in a unified manner. Due to the simple communication at element interfaces afforded by DGFEMs, elements with so-called hanging nodes can easily be treated, a fact that simplifies local mesh refinement (h -refinement); this is a major advantage of DGFEMs when compared to standard Galerkin (conforming) finite element methods (CGFEMs, for short). Indeed, this latter class of methods must exploit appropriate inter-element projections in order to ensure that the resulting finite element space satisfies the underlying continuity constraints inherent in the physical problem at hand, cf. Ref. 64, for example. Additionally, the communication at element interfaces is identical for any order of the method which simplifies the use of schemes with different polynomial orders p in adjacent elements. This allows for the variation of the order of polynomials over the computational domain (p -refinement), which in combination with h -refinement leads to so-called hp -adaptivity. Finally, in the context of domain decomposition preconditioners, DGFEMs have significant advantages over CGFEMs. Indeed, in the recent work undertaken by Antonietti and collaborators, see Refs. 4, 5, 6, 9 and 10, for example,

it is demonstrated that Schwarz-type preconditioners are particularly well-suited to DGFEMs, in the sense that uniform scalability of the underlying iterative method may be established without the need to overlap the subdomain partition of the computational mesh. This is a particularly attractive property, since the absence of overlapping subdomains reduces communication between processors on parallel machines. By (uniform) scalability, we mean that the number of iterations needed to compute the solution of the underlying system of equations is uniform, as the mesh is refined, provided that an appropriate coarse mesh solution is computed as part of the preconditioning strategy. Of course, for uniformity, the ratio of the granularity of the fine and coarse meshes must remain fixed under mesh refinement.

The major criticism of DGFEMs compared with their CGFEM counterparts is the increase in the number of degrees of freedom for a particular choice of the underlying computational finite element mesh and polynomial degree distribution. Moreover, it is typically observed that the discretization error computed using both schemes with the same discretization parameters (i.e. the same h and p) is roughly identical, at least, for the discretization of second-order elliptic partial differential equations; this naturally leads to the conclusion that DGFEMs are computationally expensive. Such arguments are typically made on the grounds of employing identical (mapped) elemental polynomial spaces within both numerical schemes. However, the flexibility of DGFEMs means that we are no longer restricted to employing standard polynomial spaces mapped from a reference or canonical frame. Indeed, DGFEMs may be constructed in a simple manner in the physical frame, without resorting to the use of local element mappings; see, for example, the recent work by Bassi *et al.* in Refs. 21–23. As noted in Ref. 21, one of the key features of employing DGFEMs based on exploiting polynomial spaces defined in the physical frame is that the order of convergence of the underlying method is independent of the element shape; see Refs. 12 and 13 for a detailed discussion of this issue, when element mappings are employed. Thereby, spaces of polynomials of total degree p , denoted by \mathcal{P}_p , may be employed, regardless of the element shape. Indeed, as we shall see in this work, when the underlying mesh consists of tensor-product elements, e.g. quadrilaterals in 2D and hexahedra in 3D, the use of \mathcal{P}_p polynomial spaces not only renders the underlying DGFEM more efficient than the standard DGFEM using tensor-product polynomials of degree p in each coordinate direction (\mathcal{Q}_p), but also more efficient than CGFEM, as the polynomial degree p increases.

The exploitation of DGFEMs using polynomial spaces defined in the physical frame, without the need to employ element mappings from a reference frame, means that DGFEMs can naturally be extended to computational meshes consisting of general element shapes; indeed, general polygonal/polyhedral elements may easily be admitted, cf. Refs. 8, 21–23, 39, 43, 54 and 72. In particular, we mention the recent work by Bassi *et al.* in Refs. 21–23 on the application of DGFEMs on meshes consisting of general agglomerated elements. A closely related technique proposed in Refs. 8 and 43 considers the development of a general class of so-called composite DGFEMs; this approach allows for the numerical approximation of

partial differential equations posed on complicated domains which contain “small” geometrical features, or so-called microstructures. Moreover, by exploiting these techniques, coarse meshes can easily be constructed for application within multi-level preconditioners, cf. Refs. 7 and 42. This flexibility of DGFEMs has also been exploited in the context of fictitious domain methods, whereby overlapping meshes are employed; indeed, the application of DGFEMs to the discretization of second-order elliptic partial differential equations on general cut-cell meshes has been considered in Ref. 51. We also refer to the work presented in the series of articles in Refs. 31–33 and 55 which exploit ideas from Nitsche’s method in Ref. 58.

In contrast, the extension of conforming finite element methods to general meshes with polygonal/polyhedral elements is far from straightforward, due to the intrinsic difficulty encountered in the design of finite element spaces with a given continuity property. Notable examples are the composite finite element method (CFE), see Refs. 44 and 45, the polygonal finite element methods (PFEM), see Refs. 67 and 68, and the extended finite element method (XFEM), see Ref. 40 and the references cited therein. These latter two approaches achieve conformity by enriching/modifying the standard polynomial finite element spaces, in the spirit of the generalized finite element framework of Babuška and Osborn in Ref. 16. Typically, the handling of non-standard shape functions carries an increase in computational effort. The recently proposed virtual element method (VEM), see Ref. 24, overcomes this difficulty achieving the extension of CGFEM to polygonal/polyhedral elements while maintaining the ease of implementation of standard FEMs; see also the very much related mimetic finite difference method in its primal, see Refs. 28, 27, and mixed, see Refs. 30, 29, 28, 34, 25 and 26, formulations.

The aim of this paper is to consider the application of DGFEMs on computational meshes consisting of general polygonal/polyhedral elements. In particular, we propose a new IP DGFEM characterized by a careful choice of the discontinuity-penalization parameter, which permits the use of polygonal/polyhedral elements such that:

- mesh element faces may have arbitrarily small measure in two dimensions;
- both mesh element faces and edges may have arbitrarily small measure in three dimensions.

The approach is based on exploiting a new inverse inequality relevant to elements with elemental interfaces whose measure is potentially much smaller than the measure of the corresponding element. On the basis of this inverse inequality, together with appropriate approximation results on general polygons/polyhedra, we derive *a priori* error bounds for the proposed IP DGFEM; for related bounds, based on employing composite DGFEMs, we refer to Ref. 8.

The rest of this paper is structured as follows. In Sec. 2, we introduce the model problem and the set of admissible subdivisions of the computational domain. In Sec. 3 we formulate the IP DGFEM; Sec. 4 presents relevant *hp*-approximation results and the new inverse inequality. The stability and *a priori* analysis of the

proposed method is then undertaken in Sec. 5. In Sec. 6, we briefly outline how the proposed IP DGFEM may be efficiently implemented. The practical performance of the IP DGFEM is studied in Sec. 7. Finally, in Sec. 8 we summarize the work presented in this paper and draw some conclusions.

2. Preliminaries

Throughout this paper, we use the following standard function spaces. For a Lipschitz domain $\omega \subset \mathbb{R}^d$, $d \geq 1$, we denote by $H^s(\omega)$ the Sobolev space of index $s \geq 0$ of real-valued functions defined on ω , endowed with the seminorm $|\cdot|_{H^s(\omega)}$ and norm $\|\cdot\|_{H^s(\omega)}$. Furthermore, we let $L^p(\omega)$, $p \in [1, \infty]$, be the standard Lebesgue space on ω , equipped with the norm $\|\cdot\|_{L^p(\omega)}$. Finally, with $|\omega|$ we denote the d -dimensional Hausdorff measure of ω .

2.1. Model problem

Let Ω be a bounded open polyhedral domain in \mathbb{R}^d , $d = 2, 3$, and let $\partial\Omega$ signify the union of its $(d - 1)$ -dimensional open faces. We consider the following model problem: find u such that

$$-\Delta u = f \quad \text{in } \Omega, \quad (2.1)$$

where $f \in L^2(\Omega)$. We divide $\partial\Omega$ into two disjoint subsets Γ_D and Γ_N whose union is $\partial\Omega$, with Γ_D nonempty and relatively open in $\partial\Omega$. With this notation, we supplement (2.1) with the boundary conditions

$$\begin{aligned} u &= g_D \quad \text{on } \Gamma_D, \\ \mathbf{n} \cdot \nabla u &= g_N \quad \text{on } \Gamma_N, \end{aligned} \quad (2.2)$$

where \mathbf{n} denotes the unit outward normal vector on the boundary $\partial\Omega$.

2.2. Finite element spaces

Let \mathcal{T} be a subdivision of the computational domain Ω into disjoint open *polygonal/polyhedral* elements κ such that $\bar{\Omega} = \bigcup_{\kappa \in \mathcal{T}} \bar{\kappa}$ and denote by h_κ the diameter of $\kappa \in \mathcal{T}$; i.e. $h_\kappa := \text{diam}(\kappa)$. In the absence of hanging nodes/edges, we define the *interfaces* of the mesh \mathcal{T} to be the set of $(d - 1)$ -dimensional facets of the elements $\kappa \in \mathcal{T}$. To facilitate the presence of hanging nodes/edges, which are permitted in \mathcal{T} , the interfaces of \mathcal{T} are defined to be the intersection of the $(d - 1)$ -dimensional facets of neighboring elements. In the case when $d = 2$, we note that the interfaces of a given element $\kappa \in \mathcal{T}$ will always consist of $(d - 1)$ -dimensional simplexes, namely, line segments. In general, for $d = 3$, this will not be the case; for the purposes of the forthcoming error analysis, we assume that each interface of an element $\kappa \in \mathcal{T}$ may be subdivided by a set of co-planar triangles. With this in mind we use the terminology “face” to refer to a $(d - 1)$ -dimensional simplex (line segment or triangle for $d = 2, 3$, respectively), which forms part of the boundary (interface) of an

element $\kappa \in \mathcal{T}$. For $d = 2$, the face and interface of an element $\kappa \in \mathcal{T}$ necessarily coincide with each other.

With this construction, we assume that a sub-triangulation into faces of each mesh interface is given if $d = 3$. We denote by Γ the union of all open mesh interfaces if $d = 2$ and the union of all open triangles belonging to the sub-triangulation of all mesh interfaces if $d = 3$. In this way, Γ is always defined as a set of $(d-1)$ -simplexes. Specific assumptions on the class of admissible meshes will be given in Sec. 4.

Further, we denote by Γ_{int} the union of all open $(d-1)$ -dimensional element faces $F \subset \Gamma$ that are contained in Ω . With this notation, we may write $\Gamma = \Gamma_D \cup \Gamma_N \cup \Gamma_{\text{int}}$, where $\Gamma_D, \Gamma_N \subset \partial\Omega$ and $\Gamma_{\text{int}} := \Gamma \setminus \partial\Omega$ are disjoint.

To each element $\kappa \in \mathcal{T}$, we associate a positive integer p_κ , henceforth referred to as the *polynomial degree* of the element κ , and collect the p_κ in the vector $\mathbf{p} := (p_\kappa : \kappa \in \mathcal{T})$. With this notation, we define the *finite element space* $S_{\mathcal{T}}^{\mathbf{p}}$ with respect to \mathcal{T} and \mathbf{p} by

$$S_{\mathcal{T}}^{\mathbf{p}} := \{u \in L^2(\Omega) : u|_\kappa \in \mathcal{P}_{p_\kappa}(\kappa), \kappa \in \mathcal{T}\},$$

where $\mathcal{P}_p(\kappa)$ denotes the space of polynomials of total degree p on κ . We stress that, by construction, the local elemental polynomial spaces employed within the definition of $S_{\mathcal{T}}^{\mathbf{p}}$ are defined in the physical space, without the need to map from a given reference or canonical frame, as is typically necessary for classical finite element methods.

3. Interior Penalty Discontinuous Galerkin Method

In this section we introduce the DGFEM discretization of the model problem (2.1), (2.2). For simplicity of presentation, we consider the popular (symmetric) IP DGFEM; this will allow us to focus on the key challenges posed by the exploitation of general computational meshes consisting of polygonal/polyhedral elements.

To this end, we define some trace operators that are required for the DGFEM. Let κ^+ and κ^- be two adjacent elements of \mathcal{T} and let \mathbf{x} be an arbitrary point on the interior face $F \subset \Gamma_{\text{int}}$ given by $F = \partial\kappa^+ \cap \partial\kappa^-$. We write \mathbf{n}_κ^+ and \mathbf{n}_κ^- to denote the outward unit normal vectors on F , relative to $\partial\kappa^+$ and $\partial\kappa^-$, respectively. Furthermore, let v and \mathbf{q} be scalar- and vector-valued functions, respectively, that are smooth inside each element κ^\pm . By (v^\pm, \mathbf{q}^\pm) , we denote the traces of (v, \mathbf{q}) on F taken from within the interior of κ^\pm , respectively. Then, the averages of v and \mathbf{q} at $\mathbf{x} \in F$ are given by

$$\langle\!\langle v \rangle\!\rangle = \frac{1}{2}(v^+ + v^-), \quad \langle\!\langle \mathbf{q} \rangle\!\rangle = \frac{1}{2}(\mathbf{q}^+ + \mathbf{q}^-),$$

respectively. Similarly, the jumps of v and \mathbf{q} at $\mathbf{x} \in F$ are given by

$$[[v]] = v^+ \mathbf{n}_{\kappa^+} + v^- \mathbf{n}_{\kappa^-}, \quad [[\mathbf{q}]] = \mathbf{q}^+ \cdot \mathbf{n}_{\kappa^+} + \mathbf{q}^- \cdot \mathbf{n}_{\kappa^-},$$

respectively. On a boundary face $F \subset \Gamma_D$, we set

$$\llbracket v \rrbracket = v^+, \quad \llbracket \mathbf{q} \rrbracket = \mathbf{q}^+, \quad \llbracket v \rrbracket = v^+ \mathbf{n},$$

with \mathbf{n} denoting the unit outward normal vector on the boundary $\partial\Omega$.

The standard symmetric IP DGFEM is given by: find $u_h \in S_T^{\mathbf{p}}$ such that

$$B(u_h, v_h) = \ell(v_h), \tag{3.1}$$

for all $v_h \in S_T^{\mathbf{p}}$. Here, the bilinear form $B : S_T^{\mathbf{p}} \times S_T^{\mathbf{p}} \rightarrow \mathbb{R}$ is given by

$$\begin{aligned} B(w, v) := & \sum_{\kappa \in \mathcal{T}} \int_{\kappa} \nabla w \cdot \nabla v \, d\mathbf{x} \\ & - \int_{\Gamma \setminus \Gamma_N} (\llbracket \nabla_h w \rrbracket \cdot \llbracket v \rrbracket + \llbracket \nabla_h v \rrbracket \cdot \llbracket w \rrbracket - \sigma \llbracket w \rrbracket \cdot \llbracket v \rrbracket) \, ds, \end{aligned}$$

and the linear functional $\ell : S_T^{\mathbf{p}} \rightarrow \mathbb{R}$ is defined by

$$\ell(v) = \int_{\Omega} f v \, d\mathbf{x} - \int_{\Gamma_D} g_D (\nabla_h v \cdot \mathbf{n} - \sigma v) \, ds + \int_{\Gamma_N} g_N v \, ds.$$

Furthermore, ∇_h denotes the elementwise gradient operator. The non-negative function $\sigma \in L^\infty(\Gamma \setminus \Gamma_N)$ is referred to as the *discontinuity-penalization parameter*; the precise definition of σ will be presented in the forthcoming analysis; cf. Lemma 5.1 below. Historically IP methods were the first to appear in the literature, see Refs. 20 and 11, based on exploiting the ideas developed by Nitsche in Ref. 58 in the context of the weak enforcement of inhomogeneous Dirichlet boundary conditions.

4. Approximation and Inverse Estimates

Before embarking on the error analysis of the *hp*-version IP DGFEM (3.1), we first derive some preliminary results. In particular, we revisit some polynomial approximation and inverse estimates in the context of general polygonal/polyhedral elements.

We require the following assumptions on the mesh.

Assumption 4.1. There exists a positive constant C_F , independent of the mesh parameters, such that

$$\max_{\kappa \in \mathcal{T}} (\text{card}\{F \subset \Gamma : F \subset \partial\kappa\}) \leq C_F.$$

Further, we require the existence of suitable coverings of the mesh, as specified below.

Definition 4.1. A *covering* $\mathcal{T}_\# = \{\mathcal{K}\}$ related to the polygonal/polyhedral mesh \mathcal{T} is a set of shape-regular d -simplexes \mathcal{K} , such that for each $\kappa \in \mathcal{T}$, there exists a $\mathcal{K} \in \mathcal{T}_\#$ such that $\kappa \subset \mathcal{K}$. Given $\mathcal{T}_\#$, we denote by $\Omega_\#$ the *covering domain* given by $\Omega_\# := (\bigcup_{\mathcal{K} \in \mathcal{T}_\#} \bar{\mathcal{K}})^\circ$, where, for a closed set $D \subset \mathbb{R}^d$, D° denotes the interior of D .

Assumption 4.2. There exists a covering \mathcal{T}_\sharp of \mathcal{T} and a positive constant \mathcal{O}_Ω , independent of the mesh parameters, such that

$$\max_{\kappa \in \mathcal{T}} \mathcal{O}_\kappa \leq \mathcal{O}_\Omega,$$

where, for each $\kappa \in \mathcal{T}$,

$$\mathcal{O}_\kappa := \text{card}\{\kappa' \in \mathcal{T} : \kappa' \cap \mathcal{K} \neq \emptyset, \mathcal{K} \in \mathcal{T}_\sharp \text{ such that } \kappa \subset \mathcal{K}\}.$$

As a consequence, we deduce that

$$\text{diam}(\mathcal{K}) \leq C_{\text{diam}} h_\kappa,$$

for each pair $\kappa \in \mathcal{T}$, $\mathcal{K} \in \mathcal{T}_\sharp$, with $\kappa \subset \mathcal{K}$, for a constant $C_{\text{diam}} > 0$, uniformly with respect to the mesh size.

We note that mesh-regularity is assumed for the mesh covering \mathcal{T}_\sharp , and *not* for the mesh \mathcal{T} . Assumption 4.2 asserts that the amount of overlap present in the covering \mathcal{T}_\sharp remains bounded as the computational mesh \mathcal{T} is refined, i.e. as the diameter of the polygonal/polyhedral elements tends to zero.

Our *hp*-approximation results and inverse estimates for polygonal/polyhedral elements are based on considering d -dimensional simplexes, cf. above, where standard results can be applied.

Definition 4.2. For each element κ in the computational mesh \mathcal{T} , we define the family \mathcal{F}_\flat^κ of all possible d -dimensional simplexes contained in κ and having at least one face in common with κ . The notation κ_\flat^F will be used to indicate a simplex belonging to \mathcal{F}_\flat^κ and sharing with $\kappa \in \mathcal{T}$ a given face F .

As far as approximation is concerned, the standard *hp*-approximation results, cf. Ref. 63, for example, are applicable by noting that each polygonal/polyhedral element is a subset of a d -simplex belonging to the covering \mathcal{T}_\sharp and that the local finite element spaces consist of polynomials *without* the use of finite element mappings. With this in mind, we recall some standard *hp*-approximation results on d -simplexes from Ref. 17 ($d = 2$) and Ref. 56 ($d = 3$); see also Refs. 18 and 35 for similar results.

Lemma 4.1. *Let $\mathcal{K} \in \mathcal{T}_\sharp$ be a d -simplex, $d = 2, 3$, of diameter $h_\mathcal{K}$. Suppose further that $v|_\mathcal{K} \in H^k(\mathcal{K})$, for some $k \geq 0$. Then, for $p \in \mathbb{N}$, there exists $\Pi_p v \in \mathcal{P}_p(\mathcal{K})$, such that*

$$\|v - \Pi_p v\|_{H^q(\mathcal{K})} \leq C \frac{h_\mathcal{K}^{s-q}}{p^{k-q}} \|v\|_{H^k(\mathcal{K})}, \quad k \geq 0, \quad (4.1)$$

for $0 \leq q \leq k$, and

$$\|v - \Pi_p v\|_{L^\infty(\mathcal{K})} \leq C \frac{h_\mathcal{K}^{s-d/2}}{p^{k-d/2}} \|v\|_{H^k(\mathcal{K})}, \quad k > d/2. \quad (4.2)$$

Here, $s = \min\{p+1, k\}$ and C is a positive constant that depends on the shape-regularity of \mathcal{K} , but is independent of v , $h_\mathcal{K}$ and p .

Functions defined on Ω can be extended to the covering domain Ω_{\sharp} based on the following standard extension operator.

Theorem 4.1. *Let Ω be a domain with a Lipschitz boundary. Then there exists a linear extension operator $\mathcal{E} : H^s(\Omega) \rightarrow H^s(\mathbb{R}^d)$, $s \in \mathbb{N}_0$, such that $\mathcal{E}v|_{\Omega} = v$ and*

$$\|\mathcal{E}v\|_{H^s(\mathbb{R}^d)} \leq C\|v\|_{H^s(\Omega)},$$

where C is a positive constant depending only on s and the shape of Ω .

Proof. See Stein.⁶⁵ □

Given the operator Π_p defined in Lemma 4.1 and the extension operator \mathcal{E} given in Theorem 4.1, we now proceed to define a suitable projection operator onto the finite element space S_T^p . To this end, for $v \in L^2(\Omega)$, we define $\tilde{\Pi}v \in S_T^p$ elementwise as follows: for each $\kappa \in \mathcal{T}$ and given the associated element $\mathcal{K} \in \mathcal{T}_{\sharp}$, such that $\kappa \subset \mathcal{K}$, cf. Definition 4.1, we write

$$\tilde{\Pi}v|_{\kappa} := \Pi_{p_{\kappa}}(\mathcal{E}v|_{\mathcal{K}})|_{\kappa}, \quad (4.3)$$

where $\Pi_{p_{\kappa}} : L^2(\mathcal{K}) \rightarrow \mathcal{P}_{p_{\kappa}}(\mathcal{K})$ as in Lemma 4.1.

Lemma 4.2. *Let $\kappa \in \mathcal{T}$, $F \subset \partial\kappa$ denote one of its faces, and $\mathcal{K} \in \mathcal{T}_{\sharp}$ denote the corresponding simplex such that $\kappa \subset \mathcal{K}$, cf. Definition 4.1. Suppose that $v \in L^2(\Omega)$ is such that $\mathcal{E}v|_{\mathcal{K}} \in H^{k_{\kappa}}(\mathcal{K})$, for some $k \geq 0$. Then, given Assumption 4.2 is satisfied, the following bounds hold*

$$\|v - \tilde{\Pi}v\|_{H^q(\kappa)} \leq C \frac{h_{\kappa}^{s_{\kappa}-q}}{p_{\kappa}^{k_{\kappa}-q}} \|\mathcal{E}v\|_{H^{k_{\kappa}}(\mathcal{K})}, \quad k_{\kappa} \geq 0, \quad (4.4)$$

for $0 \leq q \leq k_{\kappa}$, and

$$\|v - \tilde{\Pi}v\|_{L^2(F)} \leq C|F|^{1/2} \frac{h_{\kappa}^{s_{\kappa}-d/2}}{p_{\kappa}^{k_{\kappa}-1/2}} C_m(p_{\kappa}, \kappa, F)^{1/2} \|\mathcal{E}v\|_{H^{k_{\kappa}}(\mathcal{K})}, \quad k_{\kappa} > d/2, \quad (4.5)$$

where

$$C_m(p_{\kappa}, \kappa, F) = \min \left\{ \frac{h_{\kappa}^d}{\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|}, \frac{1}{p_{\kappa}^{1-d}} \right\}.$$

Here, $s_{\kappa} = \min\{p_{\kappa} + 1, k_{\kappa}\}$ and C is a positive constant, that depends on the shape-regularity of \mathcal{K} , but is independent of v , h_{κ} , and p_{κ} .

Proof. We begin by observing that

$$\|v - \tilde{\Pi}v\|_{H^q(\kappa)} = \|\mathcal{E}v - \Pi_{p_{\kappa}}(\mathcal{E}v)\|_{H^q(\kappa)} \leq \|\mathcal{E}v - \Pi_{p_{\kappa}}(\mathcal{E}v)\|_{H^q(\mathcal{K})}.$$

Thereby, bound (4.4) follows immediately upon application of (4.1), noting Assumption 4.2.

To prove (4.5), we let $\kappa_b^F \in \mathcal{F}_b^\kappa$; applying a standard scaling argument with respect to κ_b^F , the multiplicative trace inequality, and (4.4), we obtain

$$\begin{aligned} \|v - \tilde{\Pi}v\|_{L^2(F)}^2 &\leq C|F| \left(\frac{1}{|\kappa_b^F|} \|v - \tilde{\Pi}v\|_{L^2(\kappa_b^F)}^2 \right. \\ &\quad \left. + |\kappa_b^F|^{-1+1/d} \|v - \tilde{\Pi}v\|_{L^2(\kappa_b^F)} \|\nabla(v - \tilde{\Pi}v)\|_{L^2(\kappa_b^F)} \right) \\ &\leq C \frac{|F|}{|\kappa_b^F|} \left(\frac{h_\kappa}{p_\kappa} + |\kappa_b^F|^{1/d} \right) \frac{h_\kappa^{2s_\kappa-1}}{p_\kappa^{2k_\kappa-1}} \|\mathcal{E}v\|_{H^{k_\kappa}(\kappa)}^2. \end{aligned} \quad (4.6)$$

Given that $|\kappa_b^F| \leq h_\kappa^d$ and κ_b^F is arbitrary, from (4.6) we conclude that

$$\|v - \tilde{\Pi}v\|_{L^2(F)}^2 \leq C \frac{|F|}{\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|} \frac{h_\kappa^{2s_\kappa}}{p_\kappa^{2k_\kappa-1}} \|\mathcal{E}v\|_{H^{k_\kappa}(\kappa)}^2. \quad (4.7)$$

On the other hand, we observe that

$$\|v - \tilde{\Pi}v\|_{L^2(F)}^2 \leq |F| \|v - \tilde{\Pi}v\|_{L^\infty(F)}^2;$$

employing the definition of the projection operator $\tilde{\Pi}$, cf. above, together with (4.2) and Assumption 4.2 gives

$$\|v - \tilde{\Pi}v\|_{L^2(F)}^2 \leq C|F| \frac{h_\kappa^{2s_\kappa-d}}{p_\kappa^{2k_\kappa-d}} \|\mathcal{E}v\|_{H^{k_\kappa}(\kappa)}^2. \quad (4.8)$$

Now (4.5) follows by taking the minimum between the bounds (4.7) and (4.8). \square

Remark 4.1. We note that (4.7) is valid for $k_\kappa \geq 1$, but we omitted this level of generality in the statement of Lemma 4.2 in the interest of simplicity of the presentation.

Classical inverse estimates, bounding a norm of a polynomial on an element face by a norm on the element itself, are an essential ingredient in the error analysis of DGFEMs. More specifically, the stability and *a priori* error analysis of standard *hp*-version DGFEMs makes use of inverse estimates of the following form:

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv}} \frac{p^2|F|}{|\kappa|} \|v\|_{L^2(\kappa)}^2, \quad (4.9)$$

where F denotes a face of the *simplicial or quadrilateral/hexahedral* element κ and v is a polynomial of degree p . Furthermore, C_{inv} is a positive constant, which is independent of v , p , $|F|$ and $|\kappa|$.

It is possible to generalize the above inverse estimate (4.9) to the case when κ is a general polygonal/polyhedral element, based on employing (overlapping)

sub-triangulations of κ . To this end, we recall the family of simplexes \mathcal{F}_b^κ of Definition 4.2 and consider $\kappa_b^F \in \mathcal{F}_b^\kappa$. Then, for $v \in \mathcal{P}_p(\kappa)$, applying (4.9) on κ_b^F , we have

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv}} \frac{p^2|F|}{|\kappa_b^F|} \|v\|_{L^2(\kappa_b^F)}^2 \leq C_{\text{inv}} \frac{p^2|F|}{|\kappa_b^F|} \|v\|_{L^2(\kappa)}^2, \quad (4.10)$$

where C_{inv} is a positive constant, independent of v , $|F|$, $|\kappa_b^F|$ and p . Further, as in Lemma 4.2, one can select κ_b^F to have the largest possible measure $|\kappa_b^F|$, resulting in an inverse estimate of the form

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv}} \frac{p^2|F|}{\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|} \|v\|_{L^2(\kappa)}^2. \quad (4.11)$$

Apart from the obvious issue of requiring to solve a small optimization problem to evaluate accurately $\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|$, the inverse estimate (4.11) lacks sharpness in that it is not sensitive to the magnitude of the face measure relative to the measure of the polygonal element κ . For illustration, we consider the following example.

Example 4.1. We consider the domain $\kappa := \{(x, y) \in \mathbb{R}^2 : x > 0, y > 0, x + y < 1\} \cup \{(x, y) \in \mathbb{R}^2 : x > 0, y \leq 0, x - y < \epsilon\}$, for some $\epsilon > 0$; we refer to Fig. 1 for an illustration. Given $v \in \mathcal{P}_p(\kappa)$, let $F := \{(x, y) \in \mathbb{R}^2 : x - y = \epsilon\}$, then upon application of (4.11), we deduce that

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv}} \frac{\sqrt{2}p^2\epsilon}{|\kappa_b^F|} \|v\|_{L^2(\kappa)}^2, \quad (4.12)$$

with $\kappa_b^F := \{(x, y) \in \mathbb{R}^2 : x > 0, x + \epsilon y < \epsilon, x - y < \epsilon\}$. Thereby, given that $|\kappa_b^F| = \epsilon(1 + \epsilon)/2$, inequality (4.12) becomes

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv}} \frac{2\sqrt{2}p^2}{1 + \epsilon} \|v\|_{L^2(\kappa)}^2.$$

Now as $\epsilon \rightarrow 0$, the left-hand side $\|v\|_{L^2(F)}^2 \rightarrow 0$, whereas the right-hand side $\frac{2\sqrt{2}p^2}{1 + \epsilon} \|v\|_{L^2(\kappa)}^2 \rightarrow 2\sqrt{2}p^2 \|v\|_{L^2(\kappa)}^2 \neq 0$ in general.

Fig. 1. Illustration of the quadrilateral in Example 4.1.

This lack of sharpness in the inverse estimate (4.11), with respect to faces of degenerating (Hausdorff) measure, may lead to the definition of an excessively large penalization term when considering the stability of the IP DGFEM (3.1); this in turn, may result in ill-conditioning of the underlying stiffness matrix. To overcome this issue, we proceed as follows: from the first inequality in (4.10), we have

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv}} p^2 |F| \|v\|_{L^\infty(\kappa_b^F)}^2, \quad (4.13)$$

using the trivial bound $\|v\|_{L^2(\kappa_b^F)}^2 \leq |\kappa_b^F| \|v\|_{L^\infty(\kappa_b^F)}^2$. We now aim to provide an upper bound on $\|v\|_{L^\infty(\kappa_b^F)}^2$; to this end, we introduce the following definition.

Definition 4.3. Let $\tilde{\mathcal{T}}$ denote the subset of elements κ , $\kappa \in \mathcal{T}$, such that each $\kappa \in \tilde{\mathcal{T}}$ can be covered by at most $m_{\mathcal{T}}$ shape-regular simplexes K_i , $i = 1, \dots, m_{\mathcal{T}}$, such that

$$\text{dist}(\kappa, \partial K_i) < C_{as} \text{diam}(K_i)/p^2$$

and

$$|K_i| \geq c_{as} |\kappa|,$$

for all $i = 1, \dots, m_{\mathcal{T}}$, for some $m_{\mathcal{T}} \in \mathbb{N}$ and $C_{as}, c_{as} > 0$, independent of κ and \mathcal{T} .

We refer to Fig. 2 for an illustration of a polygonal element $\kappa \in \tilde{\mathcal{T}}$ covered by two triangles K_1 and K_2 . This definition allows for very general polygonal/polyhedral meshes to be included in the *a priori* error analysis given below: it is of relevance when the polygonal/polyhedral elements $\kappa \in \mathcal{T}$ contain faces/edges and faces whose (Hausdorff) measure is arbitrarily small. Note that, in particular, the polygon of Example 4.1 satisfies Definition 4.3, when $\epsilon < C_{as}/p^2$ for some constant $C_{as} > 0$.

The motivation for Definition 4.3 comes from the following result, which is a straightforward generalization (via a standard scaling argument) of Lemma 3.7 in Ref. 41.

Lemma 4.3. *Let K be a shape-regular simplex. Then, for each $v \in \mathcal{P}_p(K)$, there exists a simplex $\hat{\kappa} \subset K$, having the same shape as K and faces parallel to the faces of*

Fig. 2. Illustration of quadrilateral in Definition 4.3.

K , with $\text{dist}(\partial\hat{\kappa}, \partial K) < C_{as} \text{diam}(K)/p^2$, for some constant $C_{as} > 0$, independent of v , K and p , such that

$$\|v\|_{L^2(\hat{\kappa})} \geq \frac{1}{2} \|v\|_{L^2(K)}.$$

We are now ready to present an inverse estimate for a general polygon/polyhedron, which appears to be sharp with respect to degeneration of one or more of its faces.

Lemma 4.4. *Let $\kappa \in \mathcal{T}$, $F \subset \partial\kappa$ denote one of its faces, and $\tilde{\mathcal{T}}$ be defined as in Definition 4.3. Then, for each $v \in \mathcal{P}_p(\kappa)$, we have the inverse estimate*

$$\|v\|_{L^2(F)}^2 \leq C_{\text{INV}}(p, \kappa, F) \frac{p^2 |F|}{|\kappa|} \|v\|_{L^2(\kappa)}^2, \quad (4.14)$$

with

$$C_{\text{INV}}(p, \kappa, F) := C_{\text{inv}} \begin{cases} \min \left\{ \frac{|\kappa|}{\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|}, p^{2d} \right\}, & \text{if } \kappa \in \tilde{\mathcal{T}}, \\ \frac{|\kappa|}{\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|}, & \text{if } \kappa \in \mathcal{T} \setminus \tilde{\mathcal{T}}, \end{cases}$$

and $\kappa_b^F \in \mathcal{F}_b^\kappa$ as in Definition 4.2 and (4.11). Furthermore, C_{inv} is a positive constant, which if $\kappa \in \tilde{\mathcal{T}}$ depends on the shape regularity of the covering of κ given in Definition 4.3, but is always independent of $|\kappa|/\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|$ (and, therefore, of $|F|$), p and v .

Proof. For $\kappa \in \mathcal{T} \setminus \tilde{\mathcal{T}}$ the above inverse inequality follows immediately from (4.11). Let us now turn our attention to the case when $\kappa \in \tilde{\mathcal{T}}$. To this end, recalling Definition 4.3, for $\kappa \in \tilde{\mathcal{T}}$, we have a covering of κ by shape-regular simplexes K_j , $j = 1, \dots, m_{\mathcal{T}}$. Hence, for $\kappa_b^F \in \mathcal{F}_b^\kappa$, we have $\kappa_b^F \subset \kappa \subset \bigcup_{j=1}^{m_{\mathcal{T}}} K_j$, with $|K_j| \geq c_{as} |\kappa|$, for κ_b^F as in (4.13).

We recall the standard inverse estimate

$$\|v\|_{L^\infty(K_j)}^2 \leq C_\infty \frac{p^{2d}}{|K_j|} \|v\|_{L^2(K_j)}^2, \quad (4.15)$$

where C_∞ is a positive constant, independent of p , $|K_j|$ and v ; see, e.g. Schwab.⁶³ Employing (4.15) and Definition 4.3 again, we deduce that

$$\begin{aligned} \|v\|_{L^\infty(\kappa_b^F)}^2 &\leq \sum_{j=1}^{m_{\mathcal{T}}} \|v\|_{L^\infty(K_j)}^2 \\ &\leq C_\infty p^{2d} \sum_{j=1}^{m_{\mathcal{T}}} \frac{\|v\|_{L^2(K_j)}^2}{|K_j|} \\ &\leq \frac{C_\infty p^{2d}}{c_{as} |\kappa|} \sum_{j=1}^{m_{\mathcal{T}}} \|v\|_{L^2(K_j)}^2. \end{aligned} \quad (4.16)$$

We now define $\hat{\kappa}_j \subset K_j$ to denote the simplex relative to K_j as outlined in Lemma 4.3; thereby, exploiting Lemma 4.3 and Definition 4.3, gives

$$\frac{1}{4}\|v\|_{L^2(K_j)}^2 \leq \|v\|_{L^2(\hat{\kappa}_j)}^2 \leq \|v\|_{L^2(K_j \cap \kappa)}^2, \quad (4.17)$$

since $\hat{\kappa}_j \subset \kappa$, and hence $\hat{\kappa}_j \subset K_j \cap \kappa \subset K_j$. Combining (4.16) and (4.17), we arrive at the inequality

$$\|v\|_{L^\infty(\kappa_b^F)}^2 \leq \frac{4C_\infty m_{\mathcal{T}} p^{2d}}{c_{as} |\kappa|} \|v\|_{L^2(\kappa)}^2, \quad (4.18)$$

upon observing the trivial relation $K_j \cap \kappa \subset \kappa$. Inserting (4.18) into (4.13) gives

$$\|v\|_{L^2(F)}^2 \leq C_{\text{inv},2} \frac{p^{2d+2}|F|}{|\kappa|} \|v\|_{L^2(\kappa)}^2, \quad (4.19)$$

with $C_{\text{inv},2} = 4C_{\text{inv}}C_\infty m_{\mathcal{T}}/c_{as}$.

Taking the minimum between (4.11) and (4.19), we deduce the desired result, with a different constant, also denoted by $C_{\text{inv}} > 0$. Finally, we remark that C_{inv} is, indeed, independent of $|F|$ as is the ratio $|\kappa|/\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|$. \square

Remark 4.2. We stress that (4.14) is sharp with respect to the polynomial degree p . Indeed, as $p \rightarrow \infty$, the minimum in (4.14) will be equal to $|\kappa|/\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|$; this will be of crucial importance in the error analysis below. Further, (4.14) is sensitive with respect to the measure of the face F relative to that of the element κ . In three dimensions, face degeneration may occur when a face or one of its edges shrinks to a point (recall that here mesh faces are triangular). The inverse estimate (4.14) is sharp in both cases of face and edge degeneration. For instance going back to the setting of Example 4.1, we can see that both the left- and right-hand sides of (4.14) degenerate at the same rate as $\epsilon \rightarrow 0$. In summary, the two cases in the constant of (4.14) serves the two extremes of one degenerating face, for fixed p , and enrichment of the polynomial order p , while the element κ is kept fixed.

Remark 4.3. We point out that $1/\sup_{\kappa_b^F \subset \kappa} |\kappa_b^F|$ can be estimated in practice by selecting a simplex with face F and the remaining vertex given by any of the non-adjacent vertices to F of the polygon/polyhedron κ .

5. *A priori* Error Bound

Following the work presented in Ref. 59 for the local DGFEM, the *a priori* error analysis of the IP DGFEM (3.1) is undertaken based on introducing an appropriate inconsistent formulation. To this end, we begin by defining suitable extensions of the forms B and ℓ . In particular, we define the bilinear form

$$\begin{aligned} \tilde{B}(w, v) &:= \sum_{\kappa \in \mathcal{T}} \int_{\kappa} \nabla w \cdot \nabla v \, d\mathbf{x} - \int_{\Gamma \setminus \Gamma_N} (\{\!\!\{ \Pi_2(\nabla_h w) \}\!\!\} \cdot \llbracket v \rrbracket + \{\!\!\{ \Pi_2(\nabla_h v) \}\!\!\} \cdot \llbracket w \rrbracket) \, ds \\ &\quad + \int_{\Gamma \setminus \Gamma_N} \sigma \llbracket w \rrbracket \cdot \llbracket v \rrbracket \, ds, \end{aligned}$$

and linear functional

$$\tilde{\ell}(v) = \int_{\Omega} f v d\mathbf{x} - \int_{\Gamma_D} g_D (\Pi_2(\nabla_h v) \cdot \mathbf{n} - \sigma v) ds + \int_{\Gamma_N} g_N v ds.$$

Here, $\Pi_2 : [L^2(\Omega)]^d \rightarrow [S_T^{\mathbf{P}}]^d$ denotes the orthogonal L^2 -projection onto the finite element space $[S_T^{\mathbf{P}}]^d$. In this manner, the face integrals involving the terms $\{\{\Pi_2(\nabla_h w)\}\}$, $\{\{\Pi_2(\nabla_h v)\}\}$ and $\Pi_2(\nabla_h v)$ are well-defined for all $v, w \in \mathcal{S} := H^1(\Omega) + S_T^{\mathbf{P}}$, as these terms are now traces of elementwise polynomial functions. Moreover, it is evident that

$$\tilde{B}(w, v) = B(w, v) \quad \text{for all } w, v \in S_T^{\mathbf{P}}$$

and

$$\tilde{\ell}(v) = \ell(v) \quad \text{for all } v \in S_T^{\mathbf{P}}.$$

Thereby, $\tilde{B}(\cdot, \cdot)$ and $\tilde{\ell}(\cdot)$ are extensions of $B(\cdot, \cdot)$ and $\ell(\cdot)$ to $\mathcal{S} \times \mathcal{S}$ and \mathcal{S} , respectively. Hence, we may rewrite the discrete problem (3.1) in the following equivalent form: find $u_h \in S_T^{\mathbf{P}}$ such that

$$\tilde{B}(u_h, v_h) = \tilde{\ell}(v_h) \quad \forall v_h \in S_T^{\mathbf{P}}. \quad (5.1)$$

However, we point out that the IP DGFEM formulation (5.1) is no longer consistent due to the discrete nature of the L^2 -projection operator Π_2 .

For the proceeding error analysis, we introduce the DG-norm $||| \cdot |||$ by

$$|||w||| := \left(\sum_{\kappa \in \mathcal{T}} \int_{\kappa} |\nabla w|^2 d\mathbf{x} + \int_{\Gamma \setminus \Gamma_N} \sigma ||[w]||^2 ds \right)^{1/2},$$

for $w \in \mathcal{S}$ and $\sigma > 0$.

With this notation, we establish the following coercivity and continuity properties of the bilinear form $\tilde{B}(\cdot, \cdot)$.

Lemma 5.1. *Let $\sigma : \Gamma \setminus \Gamma_N \rightarrow \mathbb{R}_+$ be defined facewise by*

$$\sigma(\mathbf{x}) := \begin{cases} C_{\sigma} \max_{\kappa \in \{\kappa^+, \kappa^-\}} \left\{ C_{\text{INV}}(p_{\kappa}, \kappa, F) \frac{p_{\kappa}^2 |F|}{|\kappa|} \right\}, & \mathbf{x} \in F \subset \Gamma_{\text{int}}, \quad F = \partial\kappa^+ \cap \partial\kappa^-, \\ C_{\sigma} C_{\text{INV}}(p_{\kappa}, \kappa, F) \frac{p^2 |F|}{|\kappa|}, & \mathbf{x} \in F \subset \Gamma_D, \quad F = \partial\kappa \cap \Gamma_D, \end{cases} \quad (5.2)$$

with $C_{\sigma} > 0$ large enough, depending on C_F , and independent of p , $|F|$ and $|\kappa|$. Then, given Assumption 4.1 holds, we have that

$$\tilde{B}(v, v) \geq C_{\text{coer}} |||v|||^2 \quad \text{for all } v \in \mathcal{S} \quad (5.3)$$

and

$$\tilde{B}(w, v) \leq C_{\text{cont}} |||w||| |||v||| \quad \text{for all } w, v \in \mathcal{S}, \quad (5.4)$$

where C_{coer} and C_{cont} are positive constants, independent of the discretization parameters.

Proof. The proof of (5.3) follows a standard argument, though for completeness, we outline the key steps. For $v \in \mathcal{S}$, we have

$$\begin{aligned}\tilde{B}(v, v) &= \|v\|^2 - 2 \int_{\Gamma \setminus \Gamma_N} \{\Pi_2(\nabla_h v)\} \cdot [v] ds \\ &\equiv \text{I} + \text{II}.\end{aligned}\tag{5.5}$$

In order to bound term II, we first note that for $F \subset \Gamma_{\text{int}}$, we have

$$\begin{aligned}\int_F \{\Pi_2(\nabla_h v)\} \cdot [v] ds &\leq \|\sigma^{-1/2} \{\Pi_2(\nabla_h v)\}\|_{L^2(F)} \|\sigma^{1/2} [v]\|_{L^2(F)} \\ &\leq \frac{1}{2} (\|\sigma^{-1/2} \Pi_2(\nabla v^+)\|_{L^2(F)} + \|\sigma^{-1/2} \Pi_2(\nabla v^-)\|_{L^2(F)}) \\ &\quad \cdot \|\sigma^{1/2} [v]\|_{L^2(F)} \\ &\leq \epsilon (\|\sigma^{-1/2} \Pi_2(\nabla v^+)\|_{L^2(F)}^2 + \|\sigma^{-1/2} \Pi_2(\nabla v^-)\|_{L^2(F)}^2) \\ &\quad + \frac{1}{8\epsilon} \|\sigma^{1/2} [v]\|_{L^2(F)}^2;\end{aligned}$$

here, we have employed the Cauchy–Schwarz inequality, together with the arithmetic–geometric mean inequality. Employing the inverse inequality stated in Lemma 4.4, we deduce that

$$\begin{aligned}\int_F \{\Pi_2(\nabla_h v)\} \cdot [v] ds &\leq \epsilon \left(C_{\text{INV}}(p_{\kappa^+}, \kappa^+, F) \frac{p_{\kappa^+}^2 |F|}{|\kappa^+|} \|\sigma^{-1/2} \Pi_2(\nabla v)\|_{L^2(\kappa^+)}^2 \right. \\ &\quad \left. + C_{\text{INV}}(p_{\kappa^-}, \kappa^-, F) \frac{p_{\kappa^-}^2 |F|}{|\kappa^-|} \|\sigma^{-1/2} \Pi_2(\nabla v)\|_{L^2(\kappa^-)}^2 \right) \\ &\quad + \frac{1}{8\epsilon} \|\sigma^{1/2} [v]\|_{L^2(F)}^2 \\ &\leq \frac{\epsilon}{C_\sigma} (\|\nabla v\|_{L^2(\kappa^+)}^2 + \|\nabla v\|_{L^2(\kappa^-)}^2) + \frac{1}{8\epsilon} \|\sigma^{1/2} [v]\|_{L^2(F)}^2,\end{aligned}\tag{5.6}$$

where we have used the definition of the interior penalty parameter σ , cf. (5.2), together with the L^2 -stability of the projector Π_2 .

In an analogous fashion, for $F \subset \Gamma_D$, we have that

$$\int_F \{\Pi_2(\nabla_h v)\} \cdot [v] ds \leq \frac{\epsilon}{C_\sigma} \|\nabla v\|_{L^2(\kappa^+)}^2 + \frac{1}{4\epsilon} \|\sigma^{1/2} [v]\|_{L^2(F)}^2.\tag{5.7}$$

Thereby, exploiting Assumption 4.1 above, inserting (5.6) and (5.7) into (5.5) gives

$$\tilde{B}(v, v) \geq \left(1 - \frac{2C_F}{C_\sigma} \epsilon\right) \sum_{\kappa \in \mathcal{T}} \|\nabla v\|_{L^2(\kappa)}^2 + \left(1 - \frac{1}{2\epsilon}\right) \sum_{F \subset \Gamma \setminus \Gamma_N} \|\sigma^{1/2} [v]\|_{L^2(F)}^2,$$

and the bilinear form $\tilde{B}(\cdot, \cdot)$ is coercive over $\mathcal{S} \times \mathcal{S}$, assuming that $\epsilon > 1/2$ and $C_\sigma > 2C_F\epsilon$.

The proof of continuity immediately follows based on employing analogous arguments. \square

From Lemma 5.1 and Strang's second lemma, see, for example, Refs. 66 and 36, we immediately deduce the following abstract error bound.

Theorem 5.1. *Assuming the hypotheses of Lemma 5.1 hold, we have that*

$$\|u - u_h\| \leq \left(1 + \frac{C_{\text{cont}}}{C_{\text{coer}}}\right) \inf_{v \in S_T^p} \|u - v\| + \frac{1}{C_{\text{coer}}} \sup_{w \in S_T^p} \frac{|R_h(u, w)|}{\|w\|},$$

where the residual R_h is given by

$$R_h(u, w) = \tilde{B}(u, w) - \tilde{\ell}(u, w).$$

With this bound, we now proceed to prove the main result of this section.

Theorem 5.2. *Let $\Omega \subset \mathbb{R}^d$, $d = 2, 3$, be a bounded polyhedral domain, and let $\mathcal{T} = \{\kappa\}$ be a subdivision of Ω consisting of general polygonal/polyhedral elements satisfying Assumption 4.1. Further, $\mathcal{T}_\# = \{\mathcal{K}\}$ denotes the associated covering of Ω consisting of shape-regular d -simplexes as in Definition 4.1, satisfying Assumption 4.2. Let $u_h \in S_T^p$ be the IP DGFEM approximation to $u \in H^1(\Omega)$ defined by (3.1) with the discontinuity-penalization parameter given by (5.2), and suppose that $u|_\kappa \in H^{k_\kappa}(\kappa)$, $k_\kappa > 1 + d/2$, for each $\kappa \in \mathcal{T}$, such that $\mathcal{E}u|_\mathcal{K} \in H^{k_\kappa}(\mathcal{K})$, where $\mathcal{K} \in \mathcal{T}_\#$ with $\kappa \subset \mathcal{K}$. Then, the following bound holds:*

$$\|u - u_h\|^2 \leq C \sum_{\kappa \in \mathcal{T}} \frac{h_\kappa^{2(s_\kappa-1)}}{p_\kappa^{2(k_\kappa-1)}} (1 + \mathcal{G}_\kappa(F, C_{\text{INV}}, C_m, p_\kappa)) \|\mathcal{E}u\|_{H^{k_\kappa}(\mathcal{K})}^2,$$

where

$$\begin{aligned} \mathcal{G}_\kappa(F, C_{\text{INV}}, C_m, p_\kappa) &= p_\kappa h_\kappa^{-d} \sum_{F \subset \partial\kappa \setminus \Gamma_N} C_m(p_\kappa, \kappa, F) \sigma^{-1} |F| \\ &\quad + p_\kappa^2 |\kappa|^{-1} \sum_{F \subset \partial\kappa \setminus \Gamma_N} C_{\text{INV}}(p_\kappa, \kappa, F) \sigma^{-1} |F| \\ &\quad + h_\kappa^{-d+2} p_\kappa^{-1} \sum_{F \subset \partial\kappa \setminus \Gamma_N} C_m(p_\kappa, \kappa, F) \sigma |F|, \end{aligned}$$

with $s_\kappa = \min\{p_\kappa + 1, k_\kappa\}$ and $p_\kappa \geq 1$. Here, C is a positive constant which is independent of the discretization parameters.

Proof. From Theorem 5.1, we recall that the error satisfies the following bound

$$\|u - u_h\| \leq \left(1 + \frac{C_{\text{cont}}}{C_{\text{coer}}}\right) \inf_{v \in S_T^p} \|u - v\| + \frac{1}{C_{\text{coer}}} \sup_{w \in S_T^p} \frac{|R_h(u, w)|}{\|w\|}, \quad (5.8)$$

where the residual $R_h(u, w) = \tilde{B}(u, w) - \tilde{\ell}(u, w)$. To bound the first term on the right-hand side of (5.8), we exploit the approximation results stated in Lemma 4.2, together with Assumptions 4.1; to this end, we deduce that

$$\begin{aligned} \inf_{v \in S_T^{\mathbf{p}}} \|u - v\|^2 &\leq \|u - \tilde{\Pi}u\|^2 \\ &\leq C \sum_{\kappa \in \mathcal{T}} \frac{h_\kappa^{2(s_\kappa-1)}}{p_\kappa^{2(k_\kappa-1)}} \left(1 + \frac{h_\kappa^{-d+2}}{p_\kappa} \sum_{F \subset \partial\kappa \setminus \Gamma_N} C_m(p_\kappa, \kappa, F) \sigma|F| \right) \\ &\quad \cdot \|\mathcal{E}u\|_{H^{k_\kappa}(\mathcal{K})}^2. \end{aligned} \quad (5.9)$$

We now proceed to derive a bound on the residual R_h ; to this end, we first note that, upon application of integration by parts elementwise, together with the statement of the underlying partial differential (2.1), (2.2), we deduce that

$$R_h(u, w_h) = \int_{\Gamma \setminus \Gamma_N} \{\!\!\{ \nabla u - \Pi_2(\nabla u) \}\!\!\} \cdot \llbracket w_h \rrbracket ds.$$

Employing the Cauchy–Schwarz inequality gives

$$\sup_{w_h \in S_T^{\mathbf{p}}} \frac{|R_h(u, w_h)|}{\|w_h\|} \leq \left(\int_{\Gamma \setminus \Gamma_N} \sigma^{-1} |\{\!\!\{ \nabla u - \Pi_2(\nabla u) \}\!\!\}|^2 ds \right)^{1/2}. \quad (5.10)$$

Writing $\tilde{\Pi}$ to denote the vector-valued generalization of the hp -projection operator $\tilde{\Pi}$ given in (4.3), defined componentwise, we note that

$$\begin{aligned} &\int_{\Gamma \setminus \Gamma_N} \sigma^{-1} |\{\!\!\{ \nabla u - \Pi_2(\nabla u) \}\!\!\}|^2 ds \\ &\leq \int_{\Gamma \setminus \Gamma_N} \sigma^{-1} |\{\!\!\{ \nabla u - \tilde{\Pi}(\nabla u) \}\!\!\}|^2 ds + \int_{\Gamma \setminus \Gamma_N} \sigma^{-1} |\{\!\!\{ \Pi_2(\tilde{\Pi}(\nabla u) - \nabla u) \}\!\!\}|^2 ds \\ &\equiv \text{I} + \text{II}. \end{aligned} \quad (5.11)$$

To bound Term I, we proceed as above; thereby, we have

$$\text{I} \leq C \sum_{\kappa \in \mathcal{T}} \frac{h_\kappa^{2(s_\kappa-1)}}{p_\kappa^{2(k_\kappa-1)}} \frac{h_\kappa^{-d}}{p_\kappa^{-1}} \left(\sum_{F \subset \partial\kappa \setminus \Gamma_N} C_m(p_\kappa, \kappa, F) \sigma^{-1}|F| \right) \|\mathcal{E}u\|_{H^{k_\kappa}(\mathcal{K})}^2.$$

Exploiting the inverse inequality stated in Lemma 4.4, the L^2 -stability of the projector Π_2 , and the approximation results stated in Lemma 4.2 Term II may be bounded as follows:

$$\text{II} \leq C \sum_{\kappa \in \mathcal{T}} \frac{h_\kappa^{2(s_\kappa-1)}}{p_\kappa^{2(k_\kappa-1)}} \frac{|\kappa|^{-1}}{p_\kappa^{-2}} \left(\sum_{F \subset \partial\kappa \setminus \Gamma_N} C_{\text{INV}}(p_\kappa, \kappa, F) \sigma^{-1}|F| \right) \|\mathcal{E}u\|_{H^{k_\kappa}(\mathcal{K})}^2.$$

Hence, (5.10) may be bounded as follows:

$$\begin{aligned} \sup_{w_h \in S_T^p} \frac{|R_h(u, w_h)|}{|||w_h|||} &\leq C \left(\sum_{\kappa \in \mathcal{T}} \frac{h_\kappa^{2(s_\kappa-1)}}{p_\kappa^{2(k_\kappa-1)}} \left(\frac{h_\kappa^{-d}}{p_\kappa^{-1}} \sum_{F \subset \partial\kappa \setminus \Gamma_N} C_m(p_\kappa, \kappa, F) \sigma^{-1} |F| \right. \right. \\ &\quad \left. \left. + \frac{|\kappa|^{-1}}{p_\kappa^{-2}} \sum_{F \subset \partial\kappa \setminus \Gamma_N} C_{\text{INV}}(p_\kappa, \kappa, F) \sigma^{-1} |F| \right) \|\mathcal{E}u\|_{H^{k_\kappa}(\kappa)}^2 \right)^{1/2}. \end{aligned} \quad (5.12)$$

Finally, substituting (5.9) and (5.12) into (5.8), we deduce the statement of the theorem. \square

Remark 5.1. We note that the *a priori* bound stated in Theorem 5.2 for the IP DGFEM (3.1) holds without the need to impose any assumptions concerning the relative sizes of the $(d-1)$ -dimensional faces F , $F \subset \partial\kappa$, of a given polygonal/polyhedral element $\kappa \in \mathcal{T}$. Recall that for $d=3$, a face $F \subset \partial\kappa$, $\kappa \in \mathcal{T}$, is a triangle belonging to an elemental polygonal interface; the interior penalty parameter σ is constant on each such triangle, rather than the whole polygonal interface. This way, a $(d-2)$ -dimensional edge of an elemental polygonal interface is also allowed to degenerate, while the $(d-1)$ -dimensional measure of the interface can remain positive. This remarkable property highlights the advantages of the interface subdivision into triangles, which may have appeared to be somewhat arbitrary in the first instance.

Remark 5.2. As discussed above, for $d=3$, the penalty parameter σ will, in general, vary on each triangular face of a polygonal interface. This is in contrast with standard IP DGFEM error analyses, whereby a *constant* penalty is chosen on each element interface (even when hanging nodes/edges are allowed, cf., e.g. Ref. 49). Allowing for a piecewise penalty parameter on each interface leads to a potentially “finer” choice of the penalization, by eliminating the incorporation of theoretically relevant (but impractical) quantities such as, local h or p quasi-uniformity or regularity of hanging nodes, into the penalization constant. Moreover, piecewise constant penalty parameters on the constituent triangular faces of polygonal interfaces for $d=3$, are also practical in terms of implementation. Indeed, quadrature rules on such element interfaces are typically computed in a piecewise fashion anyway.

Remark 5.3. Assuming standard local quasi-uniformity assumptions, (along with quasi-uniformity of the triangulation of each polygonal element interface for $d=3$), it would be possible to choose a constant penalization parameter on each polygonal interface, thereby reverting to the “standard” IP DGFEM setting. Theorem 5.2 could be easily modified to this effect also, after summation of the interface triangular penalty contributions.

Remark 5.4. For uniform orders $p_\kappa = p \geq 1$, $h = \max_{\kappa \in \mathcal{T}} h_\kappa$, $s_\kappa = s$, $s = \min\{p+1, k\}$, $k > 1 + d/2$, we point out that, under the assumption that the diameter of the faces of each element $\kappa \in \mathcal{T}$ are of comparable size to the diameter of the corresponding element, i.e. $\text{diam}(F) \sim h_\kappa$, $F \subset \partial\kappa$, $\kappa \in \mathcal{T}$, so that $|F| \sim h_\kappa^{(d-1)}$, we get the bound

$$|||u - u_h||| \leq C \frac{h^{s-1}}{p^{k-3/2}} \|u\|_{H^k(\Omega)}.$$

Here, we have employed Theorem 4.1, together with Assumption 4.2, assuming that for such element domains $C_{\text{INV}}(p_\kappa, F) = \mathcal{O}(1)$ and $C_m(p_\kappa, F) = \mathcal{O}(1)$ uniformly for each face $F \subset \partial\kappa \setminus \Gamma_N$ for all $\kappa \in \mathcal{T}$. This bound is optimal in h and suboptimal in p by $p^{1/2}$. This error estimate coincides with the bounds derived in Refs. 49 and 62, for example, for IP DGFEMs defined on standard element domains.

6. Implementation Issues

In this section we briefly outline some of the implementation aspects of the proposed IP DGFEM, cf. (3.1).

6.1. Construction of the finite element basis functions on general polygons/polyhedra

The finite element space $S_{\mathcal{T}}^{\mathbf{p}}$ may be constructed in a number of different ways. In the case when the computational mesh \mathcal{T} consists of standard affine element domains (simplexes, parallelograms, etc.), standard polynomial bases on reference elements may simply be mapped from the reference frame to the physical element; indeed, this is the standard approach used within most finite element software packages. An alternative approach, which directly works on the physical element $\kappa \in \mathcal{T}$, without the need to refer to a given reference frame, has been proposed in the recent article by Bassi *et al.*²²; here, the elemental basis functions are constructed based on employing a Gram–Schmidt orthogonalization process applied to a given set of polynomial functions defined on κ . In this way, general polygonal/polyhedral elements may be treated in a simple fashion; indeed, Ref. 22 considers the application of this technique to general meshes consisting of agglomerated elements.

Here, we introduce an alternative approach based on employing polynomial spaces defined over the bounding box of each element; cf. Ref. 42. More precisely, given an element $\kappa \in \mathcal{T}$, we first construct the Cartesian bounding box B_κ , such that $\bar{\kappa} \subseteq \bar{B}_\kappa$, cf. Fig. 3. On the bounding box B_κ we may define a standard polynomial space $\mathcal{P}_{p_\kappa}(B_\kappa)$ spanned by a set of basis functions $\{\phi_{i,\kappa}\}$, $i = 1, \dots, \dim(\mathcal{P}_{p_\kappa}(B_\kappa))$. With this in mind, we employ tensor-product (scaled) Legendre polynomials; indeed, writing $I = (-1, 1)$, we denote the family of $L^2(I)$ -orthogonal (Legendre) polynomials by $\{L_i(x)\}_{i=0}^\infty$. Thereby, given a general interval $I_b = (x_1, x_2)$, the corresponding scaled Legendre polynomials may be defined by

$$L_i^{[b]}(x) = (1/h_b)^{1/2} L_i((x - m_b)/h_b),$$

Fig. 3. Bounding box B_κ of an element $\kappa \in \mathcal{T}$.

where $h_b = (x_2 - x_1)/2$ and $m_b = (x_1 + x_2)/2$. With this notation, a polynomial basis on B_κ may be defined as follows: writing $B_\kappa = I_1 \times I_2 \times \cdots \times I_d$, where I_j , $j = 1, \dots, d$, denotes a one-dimensional interval, the space of polynomials $\mathcal{P}_{p_\kappa}(B_\kappa)$ of total degree p_κ over B_κ is given by

$$\mathcal{P}_{p_\kappa}(B_\kappa) = \text{span}\{\phi_{i,\kappa}\}_{i=1}^{\dim(\mathcal{P}_{p_\kappa}(B_\kappa))},$$

where

$$\begin{aligned} \phi_{i,\kappa}(\mathbf{x}) &= L_{i_1}^{[1]}(x_1)L_{i_2}^{[2]}(x_2)\cdots L_{i_d}^{[d]}(x_d), \\ i_1 + i_2 + \cdots + i_d &\leq p_\kappa, \quad i_k \geq 0, \quad k = 1, \dots, d, \end{aligned}$$

and $\mathbf{x} = (x_1, x_2, \dots, x_d)$. Thereby, the polynomial basis over the general polygonal/polyhedral element κ may be defined by simply restricting the support of $\{\phi_{i,\kappa}\}$, $i = 1, \dots, \dim(\mathcal{P}_{p_\kappa}(B_\kappa))$ to κ ; i.e. the polynomial basis defined over κ is given by $\{\phi_{i,\kappa}|_\kappa\}$, $i = 1, \dots, \dim(\mathcal{P}_{p_\kappa}(B_\kappa))$.

6.2. Quadrature rules

As in Ref. 51, quadrature over general polygonal/polyhedral element domains is undertaken based on first constructing a sub-triangulation, followed by the exploitation of standard integration schemes, cf. Ref. 64, for example. Thereby, given $\kappa \in \mathcal{T}$, we first construct a non-overlapping sub-triangulation $\kappa_S = \{\tau_\kappa\}$ consisting of simplicial elements. As an example, if we consider the first term arising in the bilinear form $B(\cdot, \cdot)$, restricted to κ , then we compute

$$\begin{aligned} \int_\kappa \nabla w \cdot \nabla v d\mathbf{x} &= \sum_{\tau_\kappa \in \kappa_S} \int_{\tau_\kappa} \nabla w \cdot \nabla v d\mathbf{x} \\ &\approx \sum_{\tau_\kappa \in \kappa_S} \sum_{i=1}^q \nabla w(F_\kappa(\boldsymbol{\xi}_i)) \cdot \nabla v(F_\kappa(\boldsymbol{\xi}_i)) \det(J_{F_\kappa}(\boldsymbol{\xi}_i)) w_i, \end{aligned}$$

where $F_\kappa : \hat{\kappa} \rightarrow \tau_\kappa$ is the mapping from the reference element (simplex) $\hat{\kappa}$ to τ_κ , with Jacobi matrix J_{F_κ} , and $(\boldsymbol{\xi}_i, w_i)_{i=1}^q$ denotes the quadrature rule defined on $\hat{\kappa}$. We point out that the gradient operators are not transformed, as would be the case if the element κ was mapped to a reference frame.

We point out that alternative integration methods which do not require a sub-triangulation of the underlying polygonal/polyhedral element have recently been considered in Refs. 57, 24 and 27. For related work, we refer to Refs. 22, 55, and the references cited therein.

7. Numerical Examples

In this section we present a series of computational examples to numerically investigate the asymptotic convergence behavior of the proposed IP DGFEM on general meshes consisting of polygonal elements. Throughout this section the IP DGFEM solution u_h defined by (3.1) is computed with the constant C_σ appearing in the interior penalty parameter σ defined in Lemma 5.1 equal to 10. All the numerical examples presented in this section have been computed using the AptoFEM package (www.aptofem.com); here, the resulting system of linear equations is solved based on employing the multifrontal massively parallel solver (MUMPS), see Refs. 1–3.

7.1. Example 1

In this first example, we investigate the computational efficiency of employing the IP DGFEM on standard tensor-product elements (quadrilaterals in 2D and hexahedra in 3D) employing local polynomial bases consisting of either \mathcal{P}_p or \mathcal{Q}_p polynomials; in the following figures, these schemes will be denoted by DGFEM(P) and DGFEM(Q), respectively. Moreover, we shall compare both IP DGFEM approaches with the standard continuous Galerkin finite element method (CGFEM).

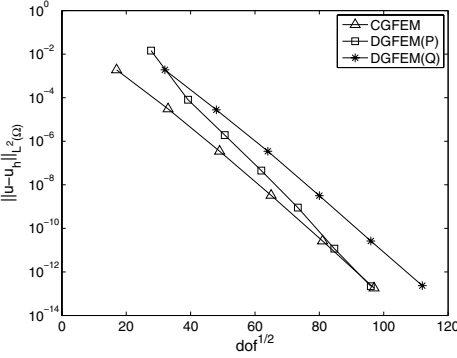

Firstly, we consider the following two-dimensional problem: let $\Omega = (0, 1)^2$ and select $f = 2\pi^2 \sin(\pi x) \sin(\pi y)$, so that the analytical solution to (2.1) is given by $u = \sin(\pi x) \sin(\pi y)$. In Fig. 4 we investigate the convergence behavior of the three schemes, namely DGFEM(P), DGFEM(Q) and CGFEM, under p -refinement for fixed h . Here, uniform square meshes consisting of 16, 64 and 256 elements are employed; for each mesh, we plot both the $L^2(\Omega)$ -norm and $H^1(\Omega)$ -seminorm of the error, against the square root of the number of degrees of freedom in the underlying finite element space, as the polynomial degree p is uniformly increased. Here, we clearly observe exponential convergence of all three methods, in the sense that, on the linear-log scale, the convergence plots become straight lines as p is increased. Moreover, we observe that the convergence lines for CGFEM and DGFEM(Q) are roughly parallel, with the former method being more efficient, in the sense that, for a given number of degrees of freedom (dof), the error measured with respect to both the $L^2(\Omega)$ -norm and $H^1(\Omega)$ -seminorm is less than the corresponding quantity computed for DGFEM(Q). However, one important observation is that, for each mesh, the slope of the convergence line for DGFEM(P), i.e. the IP DGFEM employing local \mathcal{P}_p polynomial bases, is actually steeper than the corresponding convergence line when local polynomial bases consisting of tensor-product \mathcal{Q}_p polynomials are employed. Indeed, while for moderate p , we observe that the CGFEM method is more efficient than DGFEM(P), as the polynomial degree is increased,

(b)

(c)

Fig. 4. Example 1. Comparison between IP DGFEM exploiting local \mathcal{Q}_p and \mathcal{P}_p polynomial spaces with CGFEM under p -refinement on uniform meshes consisting of square elements on $(0, 1)^2$ (2D). Left: $\|u - u_h\|_{L^2(\Omega)}$; Right: $\|u - u_h\|_{H^1(\Omega)}$; (a) 4×4 mesh; (b) 8×8 mesh; (c) 16×16 mesh.

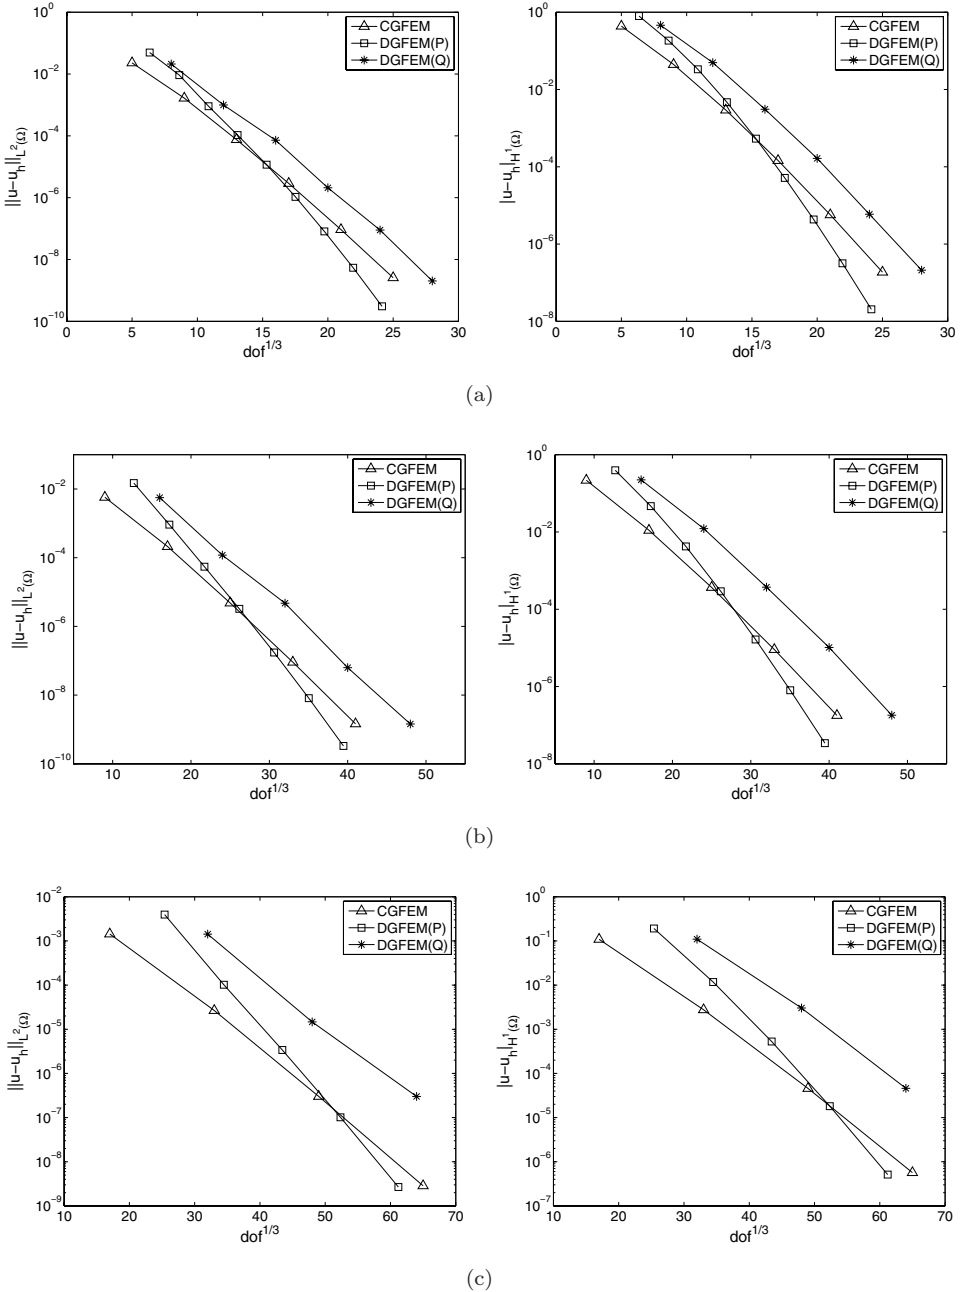

Fig. 5. Example 1. Comparison between IP DGFEM exploiting local \mathcal{Q}_p and \mathcal{P}_p polynomial spaces with CGFEM under p -refinement on uniform meshes consisting of hexahedral elements on $(0, 1)^3$ (3D). Left: $\|u - u_h\|_{L^2(\Omega)}$; Right: $|u - u_h|_{H^1(\Omega)}$; (a) $4 \times 4 \times 4$ mesh; (b) $8 \times 8 \times 8$ mesh; (c) $16 \times 16 \times 16$ mesh.

the convergence line for DGFEM(P) crosses the corresponding line for CGFEM, at least on the coarser meshes.

To investigate this behavior further, we now consider the three-dimensional variant of the above problem. To this end, we let $\Omega = (0, 1)^3$ and select $f = 3\pi^2 \sin(\pi x) \sin(\pi y) \sin(\pi z)$, so that the analytical solution to (2.1) is given by $u = \sin(\pi x) \sin(\pi y) \sin(\pi z)$. In Fig. 5 we consider the convergence of the DGFEM(P), DGFEM(Q) and CGFEM schemes under p -refinement on uniform hexahedral meshes consisting of 64, 512 and 4096 elements. As in the two-dimensional setting, we again observe that the convergence lines for both CGFEM and DGFEM(Q) are roughly parallel, with, again, the former method being more efficient in terms of leading to a smaller error for a given number of degrees of freedom. Moreover, the slope of convergence line for the DGFEM(P) scheme is not only steeper than the corresponding line for DGFEM(Q), but also that the cross-over point between DGFEM(P) becoming more efficient than CGFEM occurs much sooner.

7.2. Example 2

Following on from the previous numerical example, here we investigate the convergence behavior of the DGFEM(P) and DGFEM(Q) approaches for a non-smooth problem on hp -adaptively refined computational meshes. To this end, we let Ω be the L-shaped domain $(-1, 1)^2 \setminus [0, 1) \times (-1, 0]$, and select $f = 0$. Then, writing (r, φ) to denote the system of polar coordinates, we impose an appropriate inhomogeneous boundary condition for u so that

$$u = r^{2/3} \sin(2\varphi/3);$$

cf. Ref. 71. We note that u is analytic in $\overline{\Omega} \setminus \{\mathbf{0}\}$, but ∇u is singular at the origin; indeed, here $u \notin H^2(\Omega)$. This example reflects the typical (singular) behavior that solutions of elliptic boundary value problems exhibit in the vicinity of re-entrant corners in the computational domain.

The underlying hp -adaptive algorithm exploited within this section is based on employing the residual-based *a posteriori* error indicators proposed in Ref. 47. More precisely, the hp -adaptive meshes are constructed by first marking the elements for refinement/derefinement according to the size of these local error indicators; this is done by employing the fixed fraction strategy, with refinement and derefinement fractions set to 25% and 10%, respectively. The decision to perform local h/p -refinement/derefinement is based on employing the analyticity testing algorithm outlined in Ref. 50.

In Fig. 6 we present a comparison of the actual error, measured in terms of the DG-norm $||| \cdot |||$, for both DGFEM(P) and DGFEM(Q), versus the third root of the number of degrees of freedom in the underlying finite element space on a linear-log scale, for the sequence of meshes generated by the above hp -adaptive algorithm. For the initial refinement steps, we observe that the error in both the DGFEM(P) and DGFEM(Q) schemes is roughly comparable, for a given number of degrees of

Fig. 6. Example 2. Comparison between IP DGFEM exploiting local \mathcal{Q}_p and \mathcal{P}_p polynomial spaces based on employing adaptive hp -refinement.

freedom. However, as the adaptive algorithm proceeds, and further p -enrichment is undertaken, we observe that the convergence line for DGFEM(P) becomes steeper than the corresponding line for DGFEM(Q), cf. the previous example; consequently, DGFEM(P) becomes more efficient than DGFEM(Q), in the sense that, for a given number of degrees of freedom, the error employing the former method is smaller than the corresponding quantity computed for DGFEM(Q).

7.3. Example 3

In this final example, we now turn our attention to investigate the asymptotic behavior of the proposed IP DGFEM (DGFEM(P) using the previous notation) on a sequence of successively finer polygonal and square meshes for different values of the polynomial degree p ; we point out that in both cases we employ local spaces consisting of polynomials of degree at most p on each element κ in the mesh \mathcal{T} . The polygonal meshes are generated using the general-purpose mesh generator PolyMesher, cf. Ref. 69. Here, we employ two types of meshes generated by PolyMesher: irregular meshes (without any mesh smoothing applied), whose elements possess faces of varying size (referred to as Polygonal Elements I), and regular meshes, generated by employing a number of smoothing steps within the mesh generator (referred to as Polygonal Elements II). Typical meshes generated by PolyMesher are shown in Fig. 7.

Here, we again consider the numerical example presented in Sec. 7.1; namely, we let $\Omega = (0, 1)^2$ and select $f = 2\pi^2 \sin(\pi x) \sin(\pi y)$, so that $u = \sin(\pi x) \sin(\pi y)$. In Fig. 8 we plot the error, measured in terms of both the $L^2(\Omega)$ -norm and the

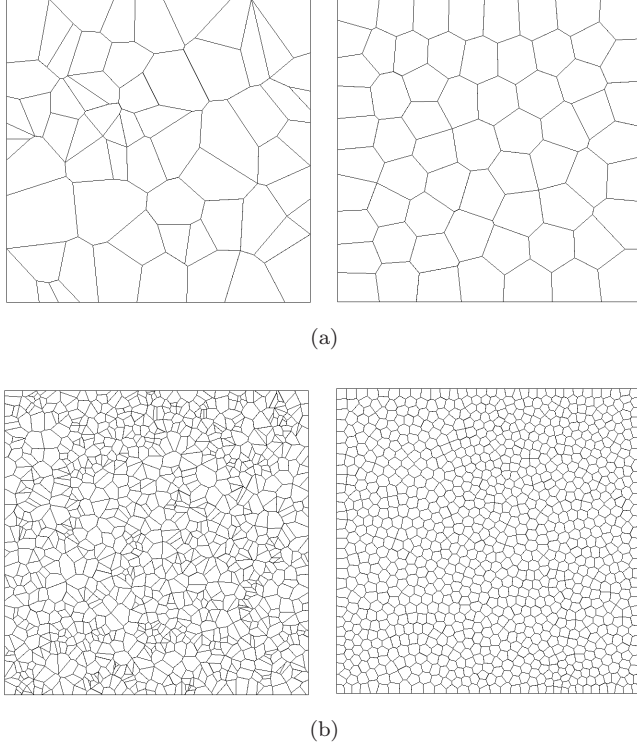

Fig. 7. Example 3. Polygonal element meshes generated using PolyMesher. Left: No mesh smoothing (Polygonal Elements I); Right: With 20 smoothing steps (Polygonal Elements II); (a) Mesh with 64 elements; (b) Mesh with 1024 elements.

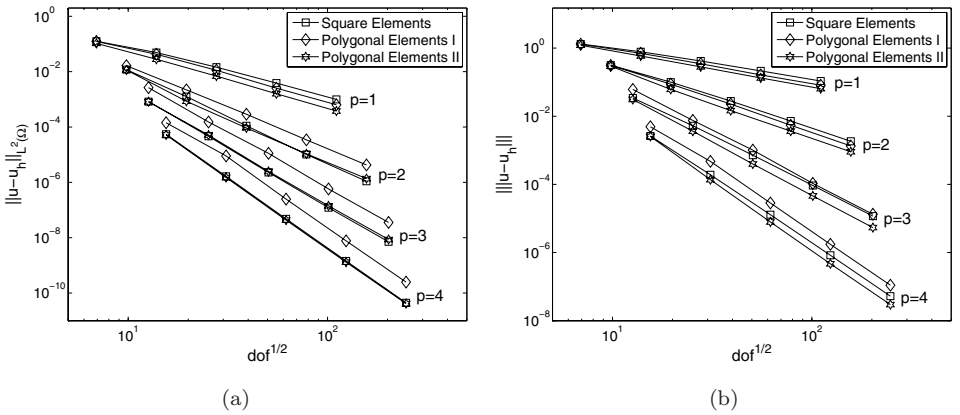

Fig. 8. Example 3. Convergence of the IP DGFEM with h -refinement: (a) $\|u - u_h\|_{L^2(\Omega)}$; (b) $|||u - u_h|||$.

DG-norm $||| \cdot |||$, against the square root of the number of degrees of freedom in the underlying finite element space $S_7^{\mathbf{p}}$ for (uniform) p between 1 and 4. Here, we clearly observe that the quantities $\|u - u_h\|_{L^2(\Omega)}$ and $|||u - u_h|||$ converge to zero at the optimal rates $\mathcal{O}(h^{p+1})$ and $\mathcal{O}(h^p)$, respectively, as the mesh size h tends to zero for each (fixed) p ; these latter results clearly confirm the optimality of Theorem 5.2. In particular, we observe that the error in the underlying IP DGFEM is smaller when Polygonal Elements II are employed, when compared to the corresponding quantity computed based on exploiting either uniform square elements or the Polygonal Elements I; this behavior is more pronounced when the error is computed with respect to the DG-norm. We remark that similar behavior was observed in Ref. 48 when the DG-norm of the error was computed on irregular quadrilateral meshes constructed by randomly splitting each of the interior nodes by a displacement of up to 10% of the local mesh size. As in Ref. 48, we attribute the improvement in the computed error, when Polygonal Elements II are employed, to the increase in interelement communication. Indeed, uniform square elements may only communicate with their four immediate neighbors, while polygonal elements possess a much greater stencil due to the increase in the number of local element faces. We note that there is some degradation of the computed error, when the sequence of irregular Polygonal Elements I are employed, as we would expect.

Finally, we investigate the convergence of the IP DGFEM under p -refinement for fixed h . To this end, in Fig. 9 we plot the DG-norm of the error against p on five different square and polygonal meshes. In each case, we observe that on the linear-log scale, the convergence plots become straight lines as the degree of the approximating polynomial is increased, thereby indicating exponential convergence in p .

Fig. 9. Example 3. Convergence of the IP DGFEM with p -refinement.

8. Concluding Remarks

We have studied the *hp*-version of the IP DGFEM for second-order elliptic partial differential equations, based on employing general computational meshes consisting of polygonal/polyhedral elements. Within this scheme polynomial bases are exploited within the physical coordinate space, without the need to map from a given reference or canonical frame. This approach is advantageous from the point of view that only element spaces consisting of polynomials of total degree p are *sufficient* to guarantee optimal convergence of the underlying method. On tensor-product meshes, the resulting scheme has been shown to, not only be computationally more efficient than standard DGFEMs based on employing full (mapped) tensor-product polynomial spaces, but also provide a competitive alternative to CGFEM, under p -enrichment.

The *a priori* error analysis presented in this paper extends and generalizes the error bounds derived in Ref. 8 for composite DGFEMs in a number of ways. In particular, the careful use of *hp*-version inverse inequalities and *hp*-version approximation properties, leads to an *a priori* error bound whose validity does *not* require any angle conditions, or any conditions on the relative sizes of the elemental interfaces on the polygonal/polyhedral mesh. Instead, the polygonal/polyhedral mesh is required to satisfy two weak assumptions (cf. Assumptions 4.1 and 4.2 which asserts in particular the existence of a shape-regular simplicial covering) for the error analysis to be valid. The resulting *hp*-version *a priori* bound is formally in accordance with respect to standard error estimates (for meshes consisting of standard simplicial/tensor-product elements) in the literature.
